Differential Mode Current and Common Mode Current

As is shown in Figure 1, currents that flow through two parallel cables that transmit signals are divided into differential mode currents and common mode currents.

- **Differential mode currents**
  These are the signal components that are intended for transmission. Since currents with equal amplitudes flow in opposing directions, the radiated electric fields have opposing directions and cancel each other out. Though the two conductors are not described as having no space in between in the actual PCB, most of the generated magnetic fields will be canceled out. As a result, the radiated electric fields will become relatively small.

- **Common mode currents**
  These are currents with the same amplitude flowing in the same direction. They are unnecessary currents that are caused by coupling between the cables and the ground due to parasitic capacitance or electromagnetic induction. Although they are very small, when compared to differential mode currents, they cause large radiated electric fields since they flow in a large loop. It is no exaggeration to say that the main cause of emission noise is common mode currents.

Eliminating only Common Mode Noise

Chip beads are often used as components for emission noise countermeasures; however, as they attenuate both common mode currents and differential mode currents, they might attenuate signal components that are necessary for operations. Common mode filters (hereinafter referred to as CMFs) can solve this problem. CMFs reduce only common mode noise, without affecting differential mode currents at all.
CMF structures can be divided into the following two types, according to the method of winding.

• Split winding
• Bifilar winding

As is shown in Figure 2, CMFs are made by winding conductive wire around a toroidal core or an EI core. The coupling coefficient or frequency characteristics of CMFs vary according to their winding methods or core types. The leakage flux is 0, i.e., all magnetic flux passes through the core, and the coupling coefficient of a CMF in which all the magnetic flux passes through the wire is 1. This is an ideal CMF that does not affect the differential mode current in any way.

The impedance frequency characteristics of a CMF with a split winding structure and a CMF with a bifilar winding structure are shown in Figure 3.

**Application of each CMF**

The types of CMFs for signal lines or DC power lines and their main electrical characteristics are shown in Table 1. In CMFs for signal lines, large common mode impedance and small differential mode impedance are required. These types of CMFs adopt a bifilar winding structure, and are used for high-speed interfaces, such as USB, IEEE1394, HDMI and DisplayPort.

In CMFs for DC power lines, not only a bifilar winding structure but a split winding structure is employed, as large differential mode impedance does not cause problems as long as the cores do not become saturated.

As for onboard applications, “CAN” and “LIN”, which are common standards for communications between ECUs, and the next-generation onboard LAN standard “FlexRay”, are examples in which CMFs (CAN/FlexRay) or LC filters (LIN) are used as EMC countermeasure components. Their aim is to provide radiation noise countermeasures and immunity against external noise to onboard equipment. In order to apply CMFs to components of onboard equipment, it is necessary to meet the demand for reliability under severe environments in vehicles. TDK provides CMFs that satisfy the reliability requirements even under high temperature loads from −40°C to +150°C.

Photo 1 is a CMF for AC power supplies. This type of CMF can reduce conducted noise between 150 kHz and 30 MHz. Even if the differential mode impedance is high, it can be used without problems as long as the core does not saturate; that is to say, it can positively be used as a countermeasure against differential noise.

Clamp filters, which will be described another chapter, are categorized as CMFs. They are mounted onto cables, which are a major cause of emission noise.
